# Energy storage cloud edge server

# Do edge servers consume a lot of energy?

Communication between base stations and edge servers consumes a lot of energy, and proper placement of edge servers can effectively reduce this energy consumption. Equations 5 and 6 define the request-response energy consumptions of the edge server .

# What is energy-efficient service scheduling in Federated edge cloud (FEC)?

This paper proposes an energy-efficient service scheduling mechanism in federated edge cloud (FEC) called ESFEC, which consists of a placement algorithm and three types of reconfiguration algorithms. Unlike traditional approaches, ESFEC places delay-sensitive services on the edge servers in nearby edge domains instead of clouds.

# How to reduce energy consumption in edge computing?

This means that a lot of energy is lost when servers are idle. As a result, the number of servers operating at poor efficiency should be lowered in order to reduce energy consumption in edge computing. To that aim, the edge server placement scheme should be optimized in order to improve edge server efficiency.

#### Can scheduling services reduce energy consumption in multi-cloud or edge clouds?

There have been a large number of research activities for scheduling services to reduce energy consumption in multi-cloud or edge clouds. However, most of them have focused on scheduling services using maximum traffic requirements regardless of their actual traffic usage.

#### How are edge servers connected?

The edge servers within an edge domain are connected by an edge switch. Each edge switch is in turn connected to aggregate switches and core switches to route traffic to the cloud servers. We assume that the cloud servers are equipped with unlimited computing capacity.

#### How much power does an edge server use?

Based on the literature, edge servers consume nearly half of the energy consumed in data centers. This power consumption is expected to exceed 600 terawatt hoursby 2025.
