

The electron configuration of sodium is $1s^2 2s^2 2p^6 3s^1$. This configuration indicates that sodium has one valence electron in its third energy level. The presence of this lone valence electron gives sodium a strong desire to lose it, as achieving a stable noble gas configuration (similar to neon) is highly favorable.

1. Introduction. As advanced energy storage devices, sodium-ion batteries (SIBs) have garnered significant attention, making remarkable progress due to the abundance and accessibility of sodium, along with its excellent energy/power density and stabilized operating voltage window [1], [2] pared to lithium ions, sodium ions can lead to sluggish transport ...

The sodium ferrite powders were obtained by the sol-gel method, through the Pechini route. In this case, the citric acid (CA) was used in excess (1:3 molar ratio between metallic ion and CA) as a chelate agent to obtain the esterification reaction [].Ethylene glycol (EG) was applied for polymerization with a molar ratio between CA-EG of 2:3 [12, 13].

Sodium-ion batteries (SIBs) are required to possess long cycle life when used for large-scale energy storage. The polyanionic $\text{Na}_4\text{MnV}(\text{PO}_4)_3$ (NMVP) reveals good cyclic stability due to its unique three-dimensional (3D) frame structure, but it still faces the challenge of interfacial degradation in practical applications. In this work, NASICON-type ...

As a new negative material for sodium-ion batteries, $\text{NaTi}_2(\text{PO}_4)_3$ has received great attention because of its excellent safety, abundant natural resources, low toxicity and two-electron reactions. However, the pure $\text{NaTi}_2(\text{PO}_4)_3$ anode material displays a bad conductivity, resulting in an inferior electrochemical performance for sodium energy storage. In ...
